The Problem

- Metadata extraction of scientific articles is a well-studied problem.
- Metadata usually refers to header information (title, authors, publisher, abstract...), bibliographic information (citations and their sub-components), document structure (sections, etc.).
- Extraction of metadata refers to processing and then *classifying* text blocks and other components of the document.
- The problem is difficult because of the wide variety of document formats that may appear.

Abstract

With the increasing use of research paper search engines, such as CiteSeer, for both literature search and hiring decisions, the accuracy of such systems is of paramount importance. This paper employs Conditional Random Fields (CRFs) for the task of extracting various common fields from the headers and citation of research papers. The basic theory of CRFs is becoming well-understood, but best-practices for applying them to real-world data requires additional exploration. This paper makes an empirical exploration of several factors, including variations on Gaussian, exponential and hyperbolic- L_3 priors for improved regularization, and several classes of features and Markov order. On a standard benchmark data set, we achieve new state-of-the-art perfor-

Previous work in information extraction from research papers has been based on two major machine learning techniques. The first is hidden Markov models (HMM) (Seymore et al., 1999; Takasu, 2003). An HMM learns a generative model over input sequence and labeled sequence pairs. While enjoying wide historical success, standard HMM models have difficulty modeling multiple non-independent features of the observation sequence. The second technique is based on discriminatively-trained SVM classifiers (Han et al., 2003). These SVM classifiers can handle many non-independent features. However, for this sequence labeling problem, Han et al. (2003) work in a two stages process: first classifying each line independently to assign it label, then adjusting these labels based on an additional classifier that examines larger windows of labels. Solving the information extraction problem in two steps loosens the tight interaction between state transitions and observations.

We regard $f(T)$ theory as an efficient tool to explain the current cosmic acceleration and associate its evolution with the known dark energy models. The numerical scheme is applied to reconstruct $f(T)$ theory from dark energy model with constant equation of state parameter and holographic dark energy model. We set the model parameters u_0 and c as describing the different evolution era and show the distinctive behavior of each case realized in $f(T)$ theory. We also present the future evolution of reconstructed $f(T)$ and find that it is consistent with the recent observations.

Abstract

Aim: Gliomas represent the most frequent neoplasm of the central nervous system. Unfortunately, surgical cure of it is practically impossible and their clinical course is primarily determined by the biological behaviors of the tumor cells. The aim of this study was to investigate the correlation of the stem cell markers Nestin and CD133 expression with the grading of gliomas, and to evaluate their prognostic value.

Methods: The tissue samples consisted of 54 high- (WHO grade III, 49 high- (WHO grade III, IV) grade gliomas, and 10 normal brain tissues. The expression levels of Nestin and CD133 proteins were detected using SABC immunohistochemical analysis. Then, the correlation of the two markers' expression with glioma grading of patients and their prognostic value were determined.

Results: Immunohistochemical analysis with anti-Nestin and anti-CD133 antibodies revealed dense and spotty staining in the tumor cells and their expression levels became significantly higher as the glioma grade advanced ($p < 0.05$). There was a positive correlation between the two markers' expression in different glioma tissues ($p < 0.001$). The low expression of the two markers significantly correlated with long survival of the glioma patients ($p < 0.05$). The survival rates of the patients with Nestin+CD133+ expression was the lowest ($p < 0.01$), and the multivariate analysis confirmed that combined expression of Nestin+CD133+ and Nestin-CD133- were independent prognostic indicators of glioma (both $p < 0.01$, Cox proportional hazard regression model).

Conclusion: These results collectively suggest that Nestin and CD133 expression may be an important feature of human glioma. A combined detection of Nestin/CD133 co-expression may benefit us in the prediction of prognosis of this tumor.

Background

Gliomas, the most frequent primary tumors in the human central nervous system, can be divided into low- and high-grade gliomas according to their morphological fea-

tures [1]. Cells of low-grade (WHO grade I and II) gliomas are well differentiated with low histological similarity to astrocyte or oligodendrocyte lineage. High-grade (WHO grade III and IV) gliomas are more anaplastic, with fea-

The Problem - Some Assumptions

- We are always dealing with PDF documents, and an OCR tool gives us access to the plaintext and OCR information (font, size, orientation,...).
- Metadata has structure and is not completely random, but it is infeasible to model deterministically \Rightarrow the task is inherently error-prone.
- There is no one-size-fits-all model for processing a full document \Rightarrow the problem must be decomposed.

There are a number of approaches to metadata extraction:

- Template-based
- Knowledge base (consult online repositories)
- Machine learning techniques (HMMs, SVMs, CRFs)

In practice, tools for metadata extraction combine these approaches (an example of which we will see later).

- 4 Initial Results
- 5 Project Objectives

Hidden Markov Models (HMMs)

- Hidden Markov Models (HMM) form a probabilistic model on sequential data.
- We have a sequence of observations, and we want to predict the “hidden” states which generate them.
- The Markov condition postulates a dependence of one state to the next as we move in time.
- HMMs have applications in fields as diverse as text processing, bioinformatics, and artificial intelligence.

Hidden Markov Models (HMMs) - Example

A well-known application of HMMs is from Natural Language Processing (NLP) - Part of Speech (PoS) tagging.

Metadata extraction is a similar problem...

Hidden Markov Models (HMMs) - Prediction

- A Hidden Markov Model factorises in the following way:

$$p(\mathbf{x}, \mathbf{y}) = \prod_{t=1}^T p(y_t | y_{t-1}) p(x_t | y_t)$$

- The probabilities $p(y_t | y_{t-1})$ are “transition” probabilities, and $p(x_t | y_t)$ “emission” probabilities, and must be calculated in advance.
- When it comes to prediction, we use dynamic programming Viterbi algorithm ($\mathcal{O}(T|S|^2)$) to maximise the conditional distribution:

$$\mathbf{y}_{prediction} = \underset{\mathbf{y}}{\operatorname{argmax}} p(\mathbf{y} | \mathbf{x}) = \underset{\mathbf{y}}{\operatorname{argmax}} \left\{ \prod_{t=1}^T p(y_t | y_{t-1}) p(x_t | y_t) \right\}$$

Take home message: we can (efficiently) predict the hidden sequence by maximising a likelihood.

2 Theory

- Hidden Markov Models
- Logistic Regression
- Conditional Random Fields

3 Grobid

4 Initial Results

5 Project Objectives

- A logistic regression is used for classifying a data sample into two (binary) or more (multi) categories, thus,

$$\hat{y}_{prediction} = \sigma(\beta^T \cdot \mathbf{x}_{sample}),$$

where \hat{y} is the prediction (represented as a probability),
 $\mathbf{x} = [x_0, x_1, \dots, x_D]^T$ is a data sample, and $\beta = [\beta_0, \beta_1, \dots, \beta_D]^T$ is the vector of parameters we must *learn*.

- We construct a (maximum log likelihood) cost function in terms of this parameter vector,

$$\mathcal{L}(\beta) = \sum_{n=1}^N y_n \beta^T \mathbf{x}_n - \log[1 + \exp(\beta^T \mathbf{x}_n)].$$

Solving a Logistic Regression

- Building a regression model is equivalent to solving a convex optimisation problem (i.e. minimising the cost function).
- We know the form of the model, and we have a set of (training) data.
- We want to choose the model parameters for which the error is minimised (think line of best fit).
- We use a numerical method to find the global minimum of error, for example, the method of gradient descent:

$$\beta^{k+1} = \beta^k - \alpha \nabla \mathcal{L}(\beta^k)$$

Take home message: we can automatically build mathematical functions for making predictions.

 - Logistic Regression
 - Conditional Random Fields
- 3 Grobid
- 4 Initial Results
- 5 Project Objectives

Conditional Random Fields (CRFs)

- CRFs belong with HMMs to a class of models called *graphical* models.
- Classifiers such as logistic regression only predict a single class; graphical models predict a full sequence.
- CRFs learn parameters like logistic regression, unlike HMMs where they are precomputed.
- Modelling the conditional probability, $p(\mathbf{y}|\mathbf{x})$ is sufficient for classification, so a CRF avoids modelling the distribution on \mathbf{x} , while allowing a freer choice of features (expressed as feature functions).
- Whereas with a HMM we model an observation's *occurrence*, with a CRF we can model richer information about an observation.

Conditional Random Fields (CRFs)

- A conditional random field factorises as,

$$p(\mathbf{y}|\mathbf{x}) = \frac{p(\mathbf{x}, \mathbf{y})}{\sum_{\mathbf{y}'} p(\mathbf{x}, \mathbf{y}')},$$

where

$$p(\mathbf{x}, \mathbf{y}) = \exp \left\{ \sum_{i \in S} \sum_{j \in S} \lambda_{ij} F_{ij}(\mathbf{y}) + \sum_{i \in S} \sum_{o \in O} \mu_{io} F_{io}(\mathbf{x}, \mathbf{y}) \right\}.$$

Choosing $F_{io}(\mathbf{x}, \mathbf{y}) \approx$ feature engineering

Conditional Random Fields (CRFs)

- Like a logistic regression we have a cost function to minimise using greatest ascent techniques and solve for model parameters.
- The optimisation algorithm is usually an approximation (l-BFGS).
- There are some further tricks during training (inference algorithms).
- Prediction is (as with HMMs) done using the Viterbi algorithm, since our factorisation is a function of both observations (\mathbf{x}) and states (\mathbf{y}).

Take home message: CRFs are very similar to HMMs: we predict in the same way, but we learn parameters through training. Modelling the conditional distribution gives us the freedom to exploit richer features.

3 Grobid

4 Initial Results

5 Project Objectives

- Grobid (GeneRation Of Bibliographic Data) is a Java-based tool for managing CRF models for metadata extraction.
- It coordinates the training and usage of a “cascade” of models, computed with a CRF engine backend.
- It may also query the web service “CrossRef” for verification.

Project Objectives

- HEP papers have some particularities, such as collaborations of thousands of authors.
- We aim to create tailored feature functions that improve performance (probably focusing on the header and segmentation).
- As well as to configure Grobid for live use.
